QP subproblem

The following code solves the QP subproblem using active set strategy

```
function [s, mu0] = solveqp(x, W, df, g, dg)
% Implement an Active-Set strategy to solve the QP problem given
by
% min      (1/2)*s'*W*s + c'*s
% s.t.     A*s-b <= 0
%
% where As-b is the linearized active constraint set

% Strategy should be as follows:
% 1-) Start with empty working-set
% 2-) Solve the problem using the working-set
% 3-) Check the constraints and Lagrange multipliers
% 4-) If all constraints are satisfied and Lagrange multipliers
are positive, terminate!
% 5-) If some Lagrange multipliers are negative or zero, find the
most negative one
%      and remove it from the active set
% 6-) If some constraints are violated, add the most violated one
to the working set
% 7-) Go to step 2

% Compute c in the QP problem formulation
c = [df(x)]';

% Compute A in the QP problem formulation
A0 = dg(x);

% Compute b in the QP problem formulation
b0 = -g(x);

% Initialize variables for active-set strategy
stop = 0;          % Start with stop = 0
% Start with empty working-set
A = [];            % A for empty working-set
b = [];            % b for empty working-set
% Indices of the constraints in the working-set
active = [];        % Indices for empty-working set

while ~stop % Continue until stop = 1
    % Initialize all mu as zero and update the mu in the working
set
    mu0 = zeros(size(g(x)));

    % Extract A corresponding to the working-set
    A = A0(active,:);
    % Extract b corresponding to the working-set
    b = b0(active);
```

```

% Solve the QP problem given A and b
[s, mu] = solve_activex(x, W, c, A, b);
% Round mu to prevent numerical errors (Keep this)
mu = round(mu*1e12)/1e12;

% Update mu values for the working-set using the solved mu
values
mu0(active) = mu;

% Calculate the constraint values using the solved s values
gcheck = A0*s-b0;

% Round constraint values to prevent numerical errors (Keep
this)
gcheck = round(gcheck*1e12)/1e12;

% Variable to check if all mu values make sense.
muccheck = 0;           % Initially set to 0

% Indices of the constraints to be added to the working set
Iadd = [];               % Initialize as empty vector
% Indices of the constraints to be added to the working set
Iremove = [];            % Initialize as empty vector

% Check mu values and set muccheck to 1 when they make sense
if (numel(mu) == 0)
    % When there no mu values in the set
    muccheck = 1;         % OK
elseif min(mu) > 0
    % When all mu values in the set positive
    muccheck = 1;         % OK
else
    % When some of the mu are negative
    % Find the most negative mu and remove it from active set
    [~,Iremove] = min(mu); % Use Iremove to remove the
constraint
end

% Check if constraints are satisfied
if max(gcheck) <= 0
    % If all constraints are satisfied
    if muccheck == 1
        % If all mu values are OK, terminate by setting stop =
1
        stop = 1;
    end
else
    % If some constraints are violated
    % Find the most violated one and add it to the working set
    [~,Iadd] = max(gcheck); % Use Iadd to add the constraint
end
% Remove the index Iremove from the working-set
active = setdiff(active, active(Iremove));

```

```
        % Add the index Iadd to the working-set
        active = [active, Iadd];

        % Make sure there are no duplications in the working-set (Keep
this)
        active = unique(active);
    end
end
```

Armijo line search

The following code performs line search on the merit function

```
function [a, w] = lineSearch(f, df, g, dg, x, s, mu_old, w_old)
    t = 0.1; % scale factor on current gradient: [0.01, 0.3]
    b = 0.8; % scale factor on backtracking: [0.1, 0.8]
    a = 1; % maximum step length

    D = s; % direction for x

    % Calculate weights in the merit function using equation (7.77)
    w = max(abs(mu_old), 0.5*(w_old+abs(mu_old)));
    % terminate if line search takes too long
    count = 0;
    while count<100
        % Calculate phi(alpha) using merit function in (7.76)
        phi_a = f(x + a*D) + w'*abs(min(0, -g(x+a*D)));

        % Calculate psi(alpha) in the line search using phi(alpha)
        phi0 = f(x) + w'*abs(min(0, -g(x))); % phi(0)
        dphi0 = df(x)*D + w'*((dg(x)*D).*(g(x)>0)); % phi'(0)
        psi_a = phi0 + t*a*dphi0; % psi(alpha)
        % stop if condition satisfied
        if phi_a<psi_a;
            break;
        else
            % backtracking
            a = a*b;
            count = count + 1;
        end
    end
end
```

Optimization Problem

```
clear;
close all;
% Here we specify the objective function by giving the function handle
% to a
% variable, for example:
f = @(x)(x(1)^2+(x(2)-3)^2); % replace with your objective function
% In the same way, we also provide the gradient of the
% objective:
df = @(x)([2*x(1), 2*x(2)-6]); % replace accordingly

g = @(x)([x(2)^2-2*x(1); (x(2)-1)^2+5*x(1)-15]);
dg = @(x)([-2 2*x(2); 5 2*x(2)-2]);

% Note that explicit gradient and Hessian information is only
% optional.
% However, providing these information to the search algorithm will
% save
% computational cost from finite difference calculations for them.

% % Specify algorithm
opt.alg = 'matlabqp'; % 'myqp' or 'matlabqp'

% Turn on or off line search. You could turn on line search once other
% parts of the program are debugged.
opt.linesearch = true; % false or true

% Set the tolerance to be used as a termination criterion:
opt.eps = 1e-3;

% Set the initial guess:
x0 = [1;1];

% Feasibility check for the initial point.
if max(g(x0))>0
    error('Infeasible initial point! You need to start from a
    feasible one!');
    return
end
% Run optimization using SQP algorithm
% Run your implementation of SQP algorithm. See mysqp.m
solution = mysqp(f, df, g, dg, x0, opt);
